# 1 Introduction

---

---

## 2 Background

---

---

### 2.1 Data Flow Analysis

---

Explain key terms such as taint, source, sink, leak

---

### 2.2 IFDS & Practical Extensions

---

---

### 2.3 Intermediate Representations

---

Explain what jimple and why it is useful to operate on an IR

- Like 25 possible statements instead of way too many instructions
- Everything is explicit. No implicit writes whatsoever

---

### 2.4 Soot

---

just short, but probably needs to be introduced before FlowDroid and especially before clinit rule

---

### 2.5 FlowDroid

---

---

## 3 Theory

---

---

### 3.1 Complexity of Data Flow Analysis

---

Explain where the run-time comes from. Depends the number of edge propagations

- "Branching factor" might be different for forwards/backwards, with some simple examples?
  - tainted = a + b. BW we don't know which was responsible for the tainted c → 2 new taints
  - Simple assignments in a strict r-to-l order: a = b. FW a, b while BW we can kill a and just go with b
- Lifetime of taints
  - Static taints are valid everywhere
  - Best practise "sanitize just before displaying" might favor backwards
- Number of taints
  - There seems to be no correlation between source count and analysis time
  - Probably also holds for sinks?
  - There might be indicator for a single app whether it is better to start at sources or sinks

---

## 3.2 Flow Functions

---

### 3.2.1 Normal Flow

In the following, we consider an assignment of the structure  $x.f^n = y.g^m$  with  $n, m \in \{0, 1\}$ .

First, we take a look at the left hand side. If the incoming taint  $t = x.f^n$

- If  $T = \{a\}$  and  $a = b$ ,  $T' = \{b\}$
- If  $T = \{b\}$  and  $a = b$ ,  $T = \{b\}$  and alias triggered
- ...

### 3.2.2 Call Flow

### 3.2.3 Return Flow

### 3.2.4 CallToReturn Flow

---

## 4 Implementation

---

---

### 4.1 Integration

---

FlowDroid is built to be extensible from the ground up. We wanted to reuse as much components of FlowDroid as possible. For the backwards analysis, we introduce unconditional taints at sinks and check for the matching access paths at sources. Facts are propagated through a reversed interprocedural control flow graph.

The methods for retrieving sources and sinks from a `SourceSinkManager` have different signatures because only at one end the access paths must match and at the other the taints are unconditional. We added the interface `IReversibleSourceSinkManager` extending the `ISourceSinkManager`. It enforces two additional methods, `getInverseSinkInfo` for introducing unconditional taints at sinks and `getInverseSourceInfo` for matching access paths at sources. `DefaultSourceSinkManager` for modelling Java, `AccessPathBasedSourceSinkManager` for modelling Android and `SummarySourceSinkManager` for summaries all now implement `IReversibleSourceSinkManager`.

Due to the flow-sensitive aliasing of FlowDroid using IFDS, FlowDroid already provides an implementation of a reversed interprocedural control flow graph called `BackwardsInfoflowCFG`. For the core - the flow functions - we created two new components implementing `IInfoflowProblem`: the backwards infoflow problem and an alias problem.

To hide the fact that we internally swapped the sources and sinks, we also created a `BackwardsInfoflowResults` extending `InfoflowResults`. The implementation is quite simple. It overwrites the `addResult` methods and reverses the constructed paths.

The modularity of FlowDroid allowed us to easily use the newly created components. We created another implementation of `IInfoflow` responsible for initialization of those closely to the already existing default implementation `Infoflow`.

---

## 4.2 Rules

---

Flow functions can get quite large, complicated to understand and hard to maintain [1]. To counteract this, FlowDroid outsources certain features into rules. These rules also provide the four flow functions and are applied in the corresponding flow function.

### 4.2.1 Backwards Source Propagation Rule

### 4.2.2 Backwards Sink Propagation Rule

### 4.2.3 Backwards Array Propagation Rule

### 4.2.4 Backwards Exception Propagation Rule

### 4.2.5 Backwards Wrapper Propagation Rule

### 4.2.6 Backwards Implicit Propagation Rule

Not implemented.

### 4.2.7 Backwards Strong Update Rule

### 4.2.8 Backwards Clinit Rule

`<clinit>` is a special method in the JVM and stands for class loader init. The function is generated by the compiler and can not be called explicitly. Examples of statements which get compiled into clinit can be seen in Figure 4.1. The invocation is implicit at the initialization phase of the class and is executed at most once for each class <sup>1</sup>. This behavior is modelled as an overapproximation in FlowDroid's default call graph algorithm SPARK. SPARK adds an edge to `<clinit>` at each statement containing a `StaticFieldRef`, `StaticInvokeExpr` or `NewExpr` <sup>2</sup>.

---

<sup>2</sup><https://github.com/soot-oss/soot/blob/59931576784b910a7d38f81910b7313aa2feafea/src/main/java/soot/jimple/toolkits/callgraph/OnFlyCallGraphBuilder.java#>

---

<pre> 1 class ClinitClass1 { 2     public static string str =         source(); 3 } </pre>	<pre> 1 class ClinitClass2 { 2     static { 3         ClinitClass2.sink(); 4     } 5 } </pre>
(a) static variable initialization	(b) static block

Figure 4.1: Examples of statements being in `<clinit>`

The need for this rule is rooted in the IFDSSolver of FlowDroid. The solver decides whether to use normal flow or call flow by calling `isCallStmt(Unit u)` on the interprocedural control-flow graph generated by Soot. Internally, this method calls `containsInvokeExpr()` on the unit object. `containsInvokeExpr()` for `AssignStmt` only returns true if the right hand side is an instance of `InvokeExpr`. Resulting, we miss the call to `<clinit>` for `AssignStmts` with `NewExpr` or `StaticFieldRef` on the right side.

The Backwards Clinit Rule manually injects an edge to the `<clinit>` method in the in-flow solver when appropriate during the analysis. Also, it lessens the overapproximation of SPARK by carefully choosing whether to inject the edge. The rule works as follows:

- If the tainted static variable is a field of the methods class: Do not inject because we will at least encounter a `NewExpr` of the same class further in the call graph.
- Else if the tainted static variable matches the `StaticFieldRef` on the right hand side: Inject the edge because we can not be sure whether we see another edge to `<clinit>`.
- Else if the class of the tainted static variable matches the class of the `NewExpr`: Inject the edge because we can not be sure whether we see another edge to `<clinit>`.

This is still an overapproximation of course. A precise solution would require bookkeeping of the first occurrence in the code of every class.

This rule has no equivalent in forwards analysis because in forwards analysis the problem is not as severe. As taints are introduced at sources, if the source statement is a static initialization as shown in Figure 4.1a, the propagation starts inside the `<clinit>` method. The solver has a `followReturnsPastSeeds` option which propagates return flows

---

for unbalanced problems, for example when the taint was introduced inside a method and therefore there was no incoming flow. This allows the forwards analysis to detect leaks originated from static variable initializations but misses leaks inside static blocks as shown in Figure 4.1b.

#### 4.2.9 Other Rules

Skip System Class Rule and Stop After First K Flows Rule are not direction-dependent. Both are shared with the forwards search and therefore use the existing implementation in FlowDroid.

Typing Propagation Rule has no backwards equivalent. We decided to implement type checking in the infowflow problem instead.

---

### 4.3 Code Optimizer

---

Before starting the analysis, FlowDroid applies code optimization to the interprocedural call graph. By default, dead code elimination and within constant value propagation is performed. Those are also applied before backwards analysis but we needed another code optimizer to handle an edge case in backwards analysis.

#### 4.3.1 AddNOPStmts

First, take a look at `StaticTestCode#static2Test` in Figure 4.2. The method and entry point `static2Test` is static and does not has any parameters. Same is true for the source method `TelephonyManager#getDeviceId`. Due to these conditions, `static2Test` in Jimple has neither identity statements nor assign statements before the source statement and therefore the source statement is the first statement in the graph. Next, a detail of FlowDroid's IFDS solver is important. The `Return` and `CallToReturn` flow function is only applied if a return site is available. When searching backwards, the source statement is the last statement and thus has no return sites. Now recall subsection 4.2.1, taints flowing into sources are registered in the `CallToReturn` flow function. Altogether, leaks can not be found if the source statement is the first statement.

---

```
1 public static void static2Test() {
2     String tainted = TelephonyManager.getDeviceId();
3     ClassWithStatic static1 = new ClassWithStatic();
4     static1.setTitle(tainted);
5     ClassWithStatic static2 = new ClassWithStatic();
6     String alsoTainted = static2.getTitle();
7
8     ConnectionManager cm = new ConnectionManager();
9     cm.publish(alsoTainted);
10 }
```

Figure 4.2: static2Test Java Code

Moving the detection of incoming taints flows into sources from the CallToReturn to the Call flow function was not an option because by default source methods are not visited. Our solution is to just add a NOP statement in such cases. This saves us from introducing new edge cases inside the flow functions which are already complex enough. Due to the entry points being known beforehand, the overhead is negligible.

---

## 5 Validation

---

---

### 5.1 DroidBench

---

### 5.1.2 Discussion

#### Button2

Found 4 paths like in forwards but built into one.

---

## 6 Evaluation

---

---

### 6.1 Configuration

---

Test setup... Test server is shared, so use less cores than available to minimize variation due to background tasks?

---

### 6.2 Performance

---

Basically the answer to RQ1: Is the backwards search efficient enough to perform analysis on real world apps?

---

### 6.3 Comparison to forwards analysis

---

Basically the answer to RQ2: Can we find a pre-analysis known parameter to decide which analysis is more efficient?

---

## 7 Related Work

---

---

## 8 Conclusion

---

---
